

Policy Uncertainty in the Market for Coal Electricity: The Case of Air Toxics Standards

Gautam Gowrisankaran

Ashley Langer

Wendan Zhang

This file details each of the code files used in the paper and included in the replication package and the order in which to run them.

1) build_cems_hourly.do:

- Louis Preonas' unit-level data didn't have pollution. (only facility level did)
- This file pulls the unit-level data again from the downloaded files, keeps pollution, and merges it into Louis' cleaned version of the unit level data.

2) merge_CEMS.do:

- This code creates our main analysis data by merging together:

- 1) EIA923 data
- 2) EIA-EPA crosswalk
- 3) PRISM weather data
- 4) State electricity demand data from PUDL
- 5) CPI data
- 6) fuel price data, year_state_FERC_AERfuel_fillin.dta,
created by Gowrisankaran, Langer, and Reguant
- 7) electricity price data by state, market_prices_state.dta,
created by Gowrisankaran, Langer, and Reguant
- 8) CEMS unit annual characteristics
- 9) hourly CEMS data

- This file outputs, in ../data/processed_data:

state_coal_share_data.dta
adoption_data.dta
ownership_data.dta
CEMS_annual.dta
CEMS_hourly_merged_data.dta

- In addition, it creates a number of intermediate data sources.

3) hourly_regressions.do: generates O&M, technology, and ramping costs.

- This code Outputs ramping_0.ster, ... , ramping_700.ster, the estimates of the ramping regressions plus estimates_om.ster, the technology and O&M cost estimates.

4) gen_profit_surface.do:

- This code generates coefficients of the profit surface

5) gen_dynamic_data.do:

- This code generates coefficients and states for C program in CSV format

6) create_halton_sequences.do: generates 3-tuple halton draws

7) reduced_form_evidence.do:

- This code generates reduced form tables and graphs from analysis data.

8) Equilibrium estimation:

adoption_estimation: compiled from adoption_estimation.c and other files

-- First, transfer files to cluster:

From code/ *.h, *.c, run*ua

Initially: Makefile, and then probably edit

From data/processed_data/ : *.csv

-- Run the estimation on the cluster with the run script (see below)

-- Create and transfer parameter files back:

Copy the best parameter vector from the output file and remove everything before the coefflabel, so rows should start with "Adoption", "Exit", etc.

On the first line, put: label, value

param`paramdate'.csv and param`paramdate'_v.csv

9) Create bootstrapped standard errors:

adoption_estimation.c:

-- Generate bootstrap draws using -g option on local computer:

adoption_estimation -v -g100 -iparamYYMMDD_v.csv

adoption_estimation -g100 -iparamYYMMDD.csv

-- Transfer bootstrapped datasets to cluster

unit_data_*B*.csv and state_year_data_*B*.csv to cluster

-- Run estimation on bootstrapped data, separately by draw number, on cluster:

-- Transfer back:

../data/bootdata/bootparam*.csv

10) Run equilibrium part of counterfactuals:

adoption_estimation:

-- Run on local computer

-- Counterfactuals can be run with adoption_estimation -v -pparam240503_v.csv

11) results_table.do: creates tables of results

12) counterfactuals.do: creates counterfactual tables

13) Figure 4 is created on the mathcha.io website. The code to create this figure (and related figures for the presentation) is in the ra.mathcha file.

To run multiple bootstrapped iterations, with draws 1-100:

Can't run these all on the same account in the same month,

so need to divide tasks across accounts on UA HPC

sbatch -a 1-100 run_boot_ua

In the file run_boot_ua, the command \$SLURM_ARRAY_TASK_ID

Using the Arizona cluster:

To transfer files to the server:

sftp alanger@filexfer.hpc.arizona.edu

cd MATS_uncertainty

Upload:

From code/ *.h, *.c, run*ua

From data/bootdata/ : *
Initially:
Makefile, and then probably edit
From data/processed_data/ : *.csv

```
ssh alanger@hpc.arizona.edu
shell
ocelote [or just don't do anything to stay on puma, which has more space]
interactive -a alanger [wait to connect to a computer]
cd MATS_uncertainty/code
make adoption_estimation
* If we switch to xdisk, we would need:
cp adoption_estimation /xdisk/alanger/MATS_uncertainty/code
cd /xdisk/alanger/MATS_uncertainty/code
```

To run the code:
sbatch run_est_ua

To run multiple bootstrapped iterations, with draws 1-5:
sbatch -a 1-5 run_boot_ua
sbatch -a 1-5 run_boot_samefedstate_ua
In the file run_boot_ua, the command \$SLURM_ARRAY_TASK_ID

Then transfer files back to local computer
